Running a 284B Parameter LLM on 3.2GB RAM with Pure C

DeepSeek-V4-Flash is a massive 284-billion-parameter language model requiring roughly 160GB of disk storage. Typically, running a model of this magnitude requires high-end server clusters equipped with massive GPU memory. However, a software engineer successfully executed the model on a standard consumer laptop equipped with very limited system RAM. By writing pure C code and utilizing memory-mapped files along with custom quantized operations, execution peaked at only 3.23GB of RAM. This milestone proves that system-level engineering and algorithmic optimization can overcome extreme hardware limits.

Why it matters:

This achievement highlights the huge potential of software-level optimization for local AI deployment. Engineering teams can dramatically cut hosting overhead by leveraging low-level memory management techniques instead of relying solely on expensive cloud GPUs. As local execution becomes viable for frontier models, privacy-first offline enterprise applications will become far easier to deploy.

Liquid AI Releases LFM2.5-DSpark Models for 3.2x Faster Inference

Liquid AI has released LFM2.5-DSpark, a set of lightweight draft models with approximately 300 million parameters. These models are engineered to work alongside larger language models through speculative decoding. Speculative decoding allows the smaller draft model to generate candidate tokens quickly, which the primary model then validates in parallel batches. Benchmark tests show that this approach increases decoding speeds by up to 3.18x compared to standard generation. Crucially, because the base model verifies all predictions, the final output remains identical to traditional greedy decoding.

Why it matters:

Reducing inference latency is one of the highest priorities for real-time AI applications and agentic workflows. By adopting speculative draft models, engineering teams can achieve faster response times while keeping cloud compute costs under control. This approach enables smoother user experiences in interactive products like voice agents and developer tools without sacrificing output quality.

EU Rules AI-Generated Content Cannot Be Copyrighted

Legal authorities in the European Union have reaffirmed that content generated purely by artificial intelligence models cannot be protected under existing copyright frameworks. Current EU intellectual property law strictly mandates that copyrightable works must reflect original human creative choices. Outputs produced autonomously by AI systems, regardless of prompt complexity, fall into the public domain by default. However, works that combine AI outputs with substantial human editing and restructuring may still qualify for protection. This ruling provides long-awaited legal clarity for creators and tech companies operating across Europe.

Why it matters:

Organizations using generative AI for software development or content creation must establish clear
